Subject: [PATCH] cgroups: implement device whitelist (v4)
Posted by serue on Mon, 17 Mar 2008 18:07:22 GMT
View Forum Message <> Reply to Message

Implement a cgroup to track and enforce open and mknod restrictions on device files. A device cgroup associates a device access whitelist with each cgroup. A whitelist entry has 4 fields. 'type' is a (all), c (char), or b (block). 'all' means it applies to all types and all major and minor numbers. Major and minor are either an integer or * for all. Access is a composition of r (read), w (write), and m (mknod).

The root device cgroup starts with rwm to 'all'. A child devcg gets a copy of the parent. Admins can then remove devices from the whitelist or add new entries. A child cgroup can never receive a device access which is denied its parent. However when a device access is removed from a parent it will not also be removed from the child(ren).

An entry is added using devices.allow, and removed using devices.deny. For instance

```
 echo 'c 1:3 mr' > /cgroups/1/devices.allow
```

allows cgroup 1 to read and mknod the device usually known as /dev/null. Doing

```
 echo a > /cgroups/1/devices.deny
```

will remove the default 'a *:* mrw' entry.

CAP_SYS_ADMIN is needed to change permissions or move another task to a new cgroup. A cgroup may not be granted more permissions than the cgroup's parent has. Any task can move itself between cgroups. This won't be sufficient, but we can decide the best way to adequately restrict movement later.

The parsing of devices.allow/deny needs to be cleaned up a bit and Documented. I'd like to get an idea whether this approach is otherwise acceptable.

Changelog:
 Mar 17 2008: Place specific device cgroup hooks next to
  security_inode_{mknod,permission} rather than using
  the security hooks.
  Also remove most of the controls over tasks moving
  between cgroups and playing with the allow and deny
  permissions.
  Switch to major:minor format.

```
  Rename devcg to 'devices' to conform to cgroup naming.
 Mar 13 2008: move the dev_cgroup support into
  capability hooks instead of having it
  as a separate security module.
  Support root_plug with devcg.
  Note that due to this change, devcg will
  not be enforcing if the dummy module is
  loaded, or if selinux is loaded without
  capabilities.
 Mar 12 2008: allow dev_cgroup lsm to be used when
  SECURITY=n, and allow stacking with SELinux
  and Smack.  Don't work too hard in Kconfig
  to prevent a warning when smack+devcg are
  both compiled in, worry about that later.

When you say cgroup->lock, you mean dev_cgroup->lock, right?
So would it be better to make it clear in the comment?

Sure. Certainly not cgrp, will use cgroup.

> > + .name = "devices",
