Subject: custom kernel build

A diff between the following configs returns nothing:

(downloadable individually from the website)

kernel-2.6.8-022stab077-x86\_64-smp.config.ovz

(included in the source RPM)

kernel-2.6.8-022stab077-x86\_64-smp.config.ovz

Yet somehow when I build the custom kernel as follows the the resulting kernels are different in size than those installed by the published rpm, ovzkernel-smp-2.6.8-022stab077.1.x86\_64.rpm.

Why?

Steps used to build:

```
rpm -ivh ovzkernel-2.6.8-022stab077.1.src.rpm
```

```
edit /usr/src/redhat/SPEC/kernel-ovz.spec
```

```
replace
```

```
%define ksubrelease 1
```

```
with
```

```
%define ksubrelease 1.custom
```

and finally

```
rpmbuild -bb kernel-ovz.spec
```

The spec files are identical as well.

Any help would be greatly appreciated.

Thanks,

Derrick

Probably it is due to different gcc versions.

Thank you for response. I was thinking that the difference in size might be a clue as to why the custom kernel will not boot.

I have made no changes to the kernel config but the custom kernel will not boot.

Did you create initrd?  
kernel.rpm installation does it at post-install stage.

Yes, install kernel using the rpm that gets built and there is an initrd.

I had to use the compat gcc version 3 compiler to build a kernel that would boot from the src rpm.
