Subject: [RFC][-mm] Memory controller hierarchy support (v1)
Posted by Balbir Singh on Sat, 19 Apr 2008 05:35:51 GMT
View Forum Message <> Reply to Message

This applies on top of 2.6.25-rc8-mm2. The next version will be applied
on top of 2.5.25-mm1.

This code is built on top of Pavel's hierarchy patches.

1. It propagates the charges upwards. A charge incurred on a cgroup
   is propagated to root. If any of the counters along the hierarchy
   is over limit, reclaim is initiated from the parent. We reclaim
   pages from the parent and the children below it. We also keep track
   of the last child from whom reclaim was done and start from there in
   the next reclaim.

TODO's/Open Questions

1. We need to hold cgroup_mutex while walking through the children
   in reclaim. We need to figure out the best way to do so. Should
   cgroups provide a helper function/macro for it?
2. Do not allow children to have a limit greater than their parents.
3. Allow the user to select if hierarchial support is required
4. Fine tune reclaim from children logic

Testing

This code was tested on a UML instance, where it compiled and worked well.

i wonder how much performance impacts this involves.

it increases the number of atomic ops per charge/uncharge and
makes the common case (success) of every charge/uncharge in a system
touch a global (ie. root cgroup's) cachelines.

if i read it correctly, it makes us hit the last child again and again.

i think you want to reclaim from all cgroups under the curr_cgroup
including eg. children's children.

```

Yes, it does. I'll run some tests to see what the overhead looks like. The multi-hierarchy feature is very useful though and one of the TODOs is to make the feature user selectable (possibly at run-time)

```

Hmm.. it should probably be set at the beginining of the loop. I'll retest

> i think you want to reclaim from all cgroups under the curr_cgroup
> including eg. children's children.
>

Yes, good point, I should break out the function, so that we can work around the
recursion problem. Charging can cause further recursion, since we check for
last_counter.

Are you going to split this patch? As is it looks rather huge :)

```

I though about it recently. Can we have a cgroup file, which will control whether to attach a res_counter to the parent? This will address the YEMEMOTO's question about the performance.

There's already a function, cgroup_lock(). But it would be nice to avoid such a heavy locking here, particularly since memory allocations can occur with cgroup_mutex held, which could lead to a nasty deadlock if the allocation triggered reclaim.

One of the things that I've been considering was to put the parent/child/sibling hierarchy explicitly in cgroup_subsys_state. This would give subsystems their own copy to refer to, and could use their own internal locking to synchronize with callbacks from cgroups that might change the hierarchy. Cpusets could make use of this too, since it has to traverse hierarchies sometimes.

> 2. Do not allow children to have a limit greater than their parents.
> 3. Allow the user to select if hierarchial support is required

My thoughts on this would be:

1) Never attach a first-level child's counter to its parent. As Yamamoto points out, otherwise we end up with extra global operations whenever any cgroup allocates or frees memory. Limiting the total system memory used by all user processes doesn't seem to be something that people are going to generally want to do, and if they really do want to they can just create a non-root child and move the whole system into that.

The one big advantage that you currently get from having all first-level children be attached to the root is that the reclaim logic automatically scans other groups when it reaches the top-level - but I think that can be provided as a special-case in the reclaim traversal, avoiding the overhead of hitting the root cgroup that we have in this patch.

2) Always attach other children's counters to their parents - if the
user didn't want a hierarchy, they could create a flat grouping rather
than nested groupings.

Paul

It's one of the TODOS

Hmm.. probably..

Very cool! I look forward to that infrastructure. I'll also look at the cpuset
code and see how to traverse the hierarchy.

I've been doing some thinking along these lines, I'll think more about this.

Yes, that's a TODO

I think multilevel cgroup is useful but this routines handling of hierarchy
seems never good. An easy idea to aginst this is making a child borrow some
amount of charge from its parent for reducing checks.
If you go this way, please show possibility to reducing overhead in your plan.

BTW, do you have ideas of attributes for children<->parent other than 'limit' ?
For example, 'priority' between childlen.

Thanks,
-Kame

Yeah - I suppose cpusets could use it, though
it's not critical. A fair bit of work already
went into cpusets so that it would not need to
traverse this hierarchy on any critical code path,
or while holding inconvenient locks.

So cpusets shouldn't be the driving motivation
for this, but it will likely be happy to go along
for the ride.
