Subject: [PATCH 3/3] i/o accounting and control  
Posted by [Andrea Righi](#) on Fri, 20 Jun 2008 10:05:35 GMT  
[View Forum Message](#) <> [Reply to Message](#)

---

Apply the io-throttle controller to the opportune kernel functions. Both accounting and throttling functionalities are performed by `cgroup_io_throttle()`.

Signed-off-by: Andrea Righi <[righi.andrea@gmail.com](mailto:righi.andrea@gmail.com)>

We do this on every submit\_bio(READ)? Ow.

I guess it's not *\_hugely\_* expensive, but the lengthy pointer hop in  
task\_subsys\_state() is going to cost.

All this could be made cheaper if we were to reduce the sampling rate:  
only call cgroup\_io\_throttle() on each megabyte of IO (for example).

```
current->amount_of_io += bio->bi_size;  
if (current->amount_of_io > 1024*1024) {  
    cgroup_io_throttle(bio->bi_bdev, bio->bi_size);  
    current->amount_of_io -= 1024 * 1024;  
}
```

but perhaps that has the potential to fail to throttle correctly when accessing multiple devices, dunno.

Bear in mind that tasks such as pdflush and kswapd will do reads when performing writeout (indirect blocks).

```

Ah, and here we see the reason for the `__cant_sleep()` hack.

It doesn't work, sorry. `in_atomic()` will return false when called under spinlock when `CONFIG_PREEMPT=n`. Your code will call `schedule_timeout_killable()` under spinlock and is deadlockable.

We need to think of something smarter here. This problem has already been largely solved at the `balance_dirty_pages()` level. Perhaps that is where the io-throttling should be cutting in?

```

```

What about ratelimiting the sampling based on i/o requests?

```

current->io_requests++;
if (current->io_requests > CGROUP_IOTHROTTLE_RATELIMIT) {
    cgroup_io_throttle(bio->bi_bdev, bio->bi_size);
    current->io_requests = 0;
}

```

The throttle would fail for large bio->bi\_size requests, but it would work also with multiple devices. And probably this would penalize tasks having a seeky i/o workload (many requests means more checks for throttling).

```

Yup. To a large degree, a 4k IO has a similar cost to a 1MB IO.  
Certainly the 1MB IO is not 256 times as expensive!

Some sort of averaging fudge factor could be used here. For example, a 1MB IO might be considered, umm 3.4 times as expensive as a 4k IO. But it varies a lot depending upon the underlying device. For a USB stick, sure, we're close to 256x. For a slow-seek, high-bandwidth device (optical?) it's getting closer to 1x. No single fudge-factor will suit all devices, hence userspace-controlled tunability would be needed here to avoid orders-of-magnitude inaccuracies.

The above

cost  $\approx$  per-device-fudge-factor \* io-size

can of course go horridly wrong because it doesn't account for seeks at all. Some heuristic which incorporates per-cgroup seekiness (in some weighted fashion) will help there.

I dunno. It's not a trivial problem, and I suspect that we'll need to get very fancy in doing this if we are to avoid an implementation which goes unusably badly wrong in some situations.

I wonder if we'd be better off with a completely different design.

<thinks for five seconds>

At present we're proposing that we look at the request stream and a-priori predict how expensive it will be. That's hard. What if we were to look at the requests post-facto and work out how expensive they were? Say, for each request which this cgroup issued, look at the start-time and the completion-time. Take the difference (elapsed time) and divide that by wall time. Then we end up with a simple percentage: "this cgroup is using the disk 10% of the time".

That's fine, as long as nobody else is using the device! If multiple cgroups are using the device then we need to do, err, something.

Or do we? Maybe not - things will, on average, sort themselves out, because everyone will slow everyone else down. It'll have inaccuracies and failure scenarios and the smarty-pants IO schedulers will get in

the way.

Interesting project, but I do suspect that we'll need a lot of complexity in there (and huge amounts of testing) to get something which is sufficiently accurate to be generally useful.
