I'm BACK!

So lets start with what the HN is etc:

Ubuntu 8.04 64bit server

Kernel = 2.6.24-21-openvz

{EDIT} Forgot to mention I use VENET not VETH interfaces on all OpenVZ machines involved

Symptoms:

Using native IPv6, I cannot allocate addresses out of the same /64 I use on the HN. I find that I have to route a second /64 allocation through the first in order for the VEs to get native connectivity. This smells like IPv6 forwarding is not working correctly, except it does work if there is a static route in place on the router. This is not the case with my CentOS 5.2 based OpenVZ machines, only Ubuntu.

Meaning:

2001:470:0:c8::1/64 is on the router's interface

2001:470:0:c8::2/64 is configured on eth0 on the server

sysctl is configured correctly to allow IPv6 packet forwarding

2001:470:0:c8::3/64 (through the end of the range) cannot be reached when configured on a VE on the Ubuntu system. It can on CentOS.

However when I statically route a second allocation (in this case 2001:470:0:c9::/64) through 2001:470:0:c8::2/64 on my router and I assign 2001:470:0:c9::1/64 (through the end of the range) to a VE, IPv6 forwarding seems to work without issue.

Notes:

Funny enough, and by no means am I comparing one virtualization platform to another, but another Ubuntu 8.04 64bit machine running Xen and a Xen kernel (2.6.24-21-xen) this bridging for IPv6 seems to work without the need for any static routes.

For reference the CentOS 5.2 OpenVZ machine I have running uses kernel

2.6.18-92.1.13.el5.028stab059.3. On THIS OpenVZ machine, I can allocate addresses out of a single /64 for the VEs, and not resort to statically routing allocations through each other.

THE QUESTION:

I'm looking for any insight into why the current Ubuntu kernel for OpenVZ behaves differently from either an older OpenVZ kernel, or a same rev Xen kernel with regards to IPv6 packet forwarding and bridging.

Nobody replied?

I found that OpenVZ does not enable proxy Neighbour Discovery for VEs. I'm using Debian lenny.

To make it work, i.e. to make my ipv6-enabled VEs reachable from my ipv6 router and/or the public internet, I had to do the following on the HN:

```
echo 1 > /proc/sys/net/ipv6/conf/all/proxy_ndp
ip -6 neigh add proxy 2001:xxxx:xxxx:xxxx::aa01 dev eth0
ip -6 neigh add proxy 2001:xxxx:xxxx:xxxx::aa02 dev eth0
ip -6 neigh add proxy 2001:xxxx:xxxx:xxxx::aa03 dev eth0
etc ...
```

It might be necessary to also do:

```
echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

I don't know why vzctl does not do this automatically like it does for ipv4.

This one solved the same issue for me on centos 6.4.

Sorry for resurrecting the thread, but it was really useful.

Thanks!
