	dummy	0	0	0	0	0
	dummy	0	0	0	0	0
	numiptent	10	10	200	200	0

As you can see, alot of failcounts on our privvmpages. Some processes do get killed and to my knowledge, I can't go any higher on the pages.. As I'm pretty new to this kind of stuff, what am I doing wrong?

The HN has 3,2GB of RAM and about 3,5GB of swap..

privvmpages is allocated (but not always used) memory. Many apps (such as Java) tend to allocate much more than they actually use.

Rules (constraints) of privvmpages allocation for multiple containers are described here:
[http://wiki.openvz.org/UBC_systemwide_configuration#Allocate d_memory](http://wiki.openvz.org/UBC_systemwide_configuration#Allocate_d_memory)

You can use vzmemcheck to see if you are on the safe side.

Well, on our node there's only one container. I want it to give the maximum amount of resources available. I already calculated the privvmpages and oomguarpages to 0.85% of the system resources but it still seem to swap a lot AND the average cpu wait is around 30%. Is this normal?

privvmpages can be set up to RAM+swap, i.e. if you have 4G RAM and 8G swap you can set privvmpages to about 12G, sometimes even more.

In other words, if you only have one container (and the host system) your privvmpages is way too low.
