I am trying to rebuild the kvm-kmod kernel module for the new openvz kernel but it seems some functions are missing:

rpmbuild --rebuild kvm-83-105.el5_4.9.src.rpm --define "kversion
2.6.18-164.2.1.el5.028stab066.7" --nodeps

Is it even posible use kvm with the openvz patched 2.6.18 kernel?

I tried to do that, but I saw there is no kvm on this kernel.

I have created a small patch, it works to me, but it would be good to have some comments from the OpenVZ developers:

kvm-openvz.spec (apply on /usr/src/redhat/SPECS/kvm.spec)

We haven't started testing KVM on this kernel yet, but plan to do so next week or so. I'll report if we find anything unusual.

Some response from openVZ developers would be nice, though.

Perhaps we should file a bug in the openvz bugzilla for this KVM issue?

I get a kernel panic very soon. Any ideas?

I have the same panic here, when I start the ksm service. It seems there is a page that is

allocated on different path without "charging" it, and when the memory manager try to free that page (free_hot_cold_page), it crashes.

The relevant source lines are here:

/kernel/ub/ub_mem.c

```
/*
 * Pages accounting
 */

int ub_page_charge(struct page *page, int order, gfp_t mask)
{
      struct user_beancounter *ub;
      unsigned long flags;

      ub = NULL;
      if (!(mask & __GFP_UBC))
            goto out;

      ub = get_beancounter(get_exec_ub());
      if (ub == NULL)
            goto out;

      local_irq_save(flags);
      if (ub_kmemsize_charge(ub, CHARGE_ORDER(order),
                  (mask & __GFP_SOFT_UBC ? UB_SOFT : UB_HARD)))
            goto err;

      inc_pages_charged(ub, order);
      local_irq_restore(flags);
out:
      BUG_ON(page_ub(page) != NULL);
      page_ub(page) = ub;
      return 0;

err:
      local_irq_restore(flags);
      BUG_ON(page_ub(page) != NULL);
      put_beancounter(ub);
      return -ENOMEM;
}

void ub_page_uncharge(struct page *page, int order)
{
      struct user_beancounter *ub;
      unsigned long flags;
```

```c
        ub = page_ub(page);
        if (ub == NULL)
                return;

        BUG_ON(ub->ub_magic != UB_MAGIC);
        dec_pages_charged(ub, order);
        local_irq_save(flags);
        ub_kmemsize_uncharge(ub, CHARGE_ORDER(order));
        local_irq_restore(flags);
        put_beancounter(ub);
        page_ub(page) = NULL;
}
```

ksm/ksm_main.c

```c
static int try_to_merge_two_pages_alloc(struct mm_struct *mm1,
                        struct page *page1,
                        struct mm_struct *mm2,
                        struct page *page2,
                        unsigned long addr1,
                        unsigned long addr2)
{
        struct vm_area_struct *vma;
        pgprot_t prot;
        int ret = 1;
        struct page *kpage;

        kpage = alloc_page(GFP_HIGHUSER);
        if (!kpage)
                return ret;
        down_read(&mm1->mmap_sem);
        vma = find_vma(mm1, addr1);
        if (!vma) {
                put_page(kpage);
                up_read(&mm1->mmap_sem);
                return ret;
        }
        prot = vma->vm_page_prot;
        pgprot_val(prot) &= ~_PAGE_RW;

        copy_user_highpage(kpage, page1, addr1);
        ret = try_to_merge_one_page(mm1, vma, page1, kpage, prot);
        up_read(&mm1->mmap_sem);
```
[..]

However the alloc_page calls __alloc_page function, that is "charged". Any idea?

```

We have been rebuilding kvm module for openvz RHEL5 kernels and running these for 2 months - so far no kernel crashes, servers have been stable. We also build a bare-metal CentOS based ISO installer and are working on management solutions as well. ISO installer project can be found on http://opennode.sourceforge.net/

Thanks for the update. The same status here: stable server, no crashes.
