Hi,

I am getting rc code -2 from the vzctl when starting the container. It seems the issue is with the vps lock. Also I am searching for an option to start the VPS like --skip-lock with vzctl.

What the the return code -2 from vzctl means ?

What the the best method to start the VPS with a lock file ?

deleting the lock file before starting the VPS is a good option ?

Hello,

is it possible to find out what kind of lock vzctl complains about. You may try to use "strace" utility. Lock files contain the PID which can help you to catch the process that is holding a particular lock.
