I created a VPS using the precreated opensuse10 64bit template but wget is completely missing from it, "bash command not found".

Is this normal? Does anyone else run into this problem? How do I get wget into the system? Should I recreate the VPS?

Any help would be greatly appreciated. Thanks!

You can install any package to a VE using any standard tools that are included into the distro you are using for that VE. In case of opensuse this would either be yast or plain old rpm I guess.
