I'm very new to OpenVZ. I installed using the instructions on the site and followed the directions to the letter. The server is in a data center that I don't have access to. It's froze twice and the engineer's in the data center say it's a kernel panic although nothing is in /var/log/messages

I mainly want to make sure I'm using the right kernel

```
[root@carl log]# rpm -qa | egrep 'ovz|vzctl'
vzctl-lib-3.0.23-1
vzctl-3.0.23-1
vzctl-lib-3.0.23-1
ovzkernel-2.6.18-164.2.1.el5.028stab066.10
```

```
[root@carl log]# uname -a
Linux carl.chainhost.com 2.6.18-164.2.1.el5.028stab066.10 #1 SMP Sat Dec 12 18:52:53 MSK
2009 x86_64 x86_64 x86_64 GNU/Linux
```

```
[root@carl log]# cat /proc/vz/version
028stab066.10
```

This server is running a Core2Quad processor, 8GB of RAM and software RAID 1.

The OS is CentOS 5.4 64-bit (x86_64)

I suggest you set up a network console as described in the wiki, if possible.

http://wiki.openvz.org/Remote_console_setup

Thanks for the tip! I just got confirmation this was a memory issue and it has been resolved.

Thanks again!
