Hi,

We have six file servers, all virtualised on OpenVZ, all identical in set-up. Even the hardware of the host servers are pretty much identical. Host kernels are 2.6.18-12-fza-amd64 (all hosts) and the fileserver OS is Ubuntu 8.04 (all fileserver).

The problem is that the users of one of the fileserver are reporting Windows 'Delayed Write Failed' messages. Windows (XP Pro) is almost certainly not the issue - every user is using identical 'imaged' Windows installations.

Can anyone suggest what might be wrong? User_beancounters checks out fine - no reported resource shortages. The affected fileserver is in many ways one of our 'quieter' ones - which confuses the issue even more!! I doubt that this is an OpenVZ problem - but I thought I'd better ask here just in case.

TIA

Huw

My guess is that it's a samba problem...

Care to elaborate? It's possible I guess but I find that a little strange seeing as all the other fileserver have identical set-ups :-/

Huw

The openvz kernel is the same in all the other boxes, too. I think it's more likely to be a samba configuration issue, or a network problem.

My only suggestion is to try to reproduce the error and after that use tcpdump to find the differences between a good session and a bad one.
