
Subject: kernel-debuginfo ovz-kernel; kernel panic

Hi, all.
A few questions.

1. Does anybody know, where I can obtain the kernel-debuginfo and kernel-debuginfo-common packages for stable ovz-kernel ?
(2.6.18-238.5.1.el5.028stab085.2)

2.
After upgrading the server for 16G ram, I started to see a lot of kernel panics.

The hardware is desktop grade,
AMD Phenom(tm) II X4 945 Processor
MSI 770-C45
16G of mem.

OS: CentOS 5.5 with the latest openvz kernel.

However, I've checked the mem with memtest86+, and it shows no errors.
And I've successfully got a kernel dump (with kdump), so it seems to be related to some software errors.

With 8G of mem, the server was running 1 year without any errors.

Any suggestions ?

PS. also in the messages:

kernel: amd64_edac: probe of 0000:00:18.2 failed with error -22

kernel: EDAC amd64_edac: Ver: 3.2.0 May 18 2010

kernel: EDAC amd64: This node reports that Memory ECC is currently disabled, set F3x44[22] (0000:00:18.3).

kernel: EDAC amd64: WARNING: ECC is disabled by BIOS. Module will NOT be loaded.

I'm sorry, build of debuginfo packages is currently broken in spec.
however you can rebuild kernel with default config with enabled debuginfo option

Please catch kernel panic messages and report to bugzilla.openvz.org

IMHO it isn't fatal messages, you can ignore it.

thank you,
Vasily Averin

Thanks for your reply.

1. First I've realized that the newest version of ovz kernel has appeared.
And also there is an ovzkernel-debug package present.

Could you tell me, what the package ovzkernel-debug means ?
Will it enough for debugging the kernel coredump with crash utility ?

2. Following your advice,
I've rebuilt the kernel with the next way:

```
yum install auto-buildrequires gcc redhat-rpm-config
wget current_kernel_src.rpm
rpm -ivh current_kernel_src.rpm
```

```
cd /usr/src/redhat/SPECS/
```

```
set in kernel-ovz.spec:
%define _without_debuginfo 0
```

```
rpmbuild -bp kernel-ovz.spec
rpmbuild -ba --target=`uname -i` kernel-ovz.spec
```

And currently I have a choose what kernel version I need to install:

```
# ls -l ../RPMS/x86_64/
ovzkernel-2.6.18-238.5.1.el5.028stab085.3.x86_64.rpm
ovzkernel-debug-2.6.18-238.5.1.el5.028stab085.3.x86_64.rpm
ovzkernel-devel-2.6.18-238.5.1.el5.028stab085.3.x86_64.rpm
ovzkernel-xen-2.6.18-238.5.1.el5.028stab085.3.x86_64.rpm
ovzkernel-xen-devel-2.6.18-238.5.1.el5.028stab085.3.x86_64.r pm
```

And I'm a little confused:

use the official openvz builded ovzkernel-debug \ ovzkernel
or install my own builded kernel ovzkernel or ovzkernel-debug ...

3. It's good for current versions of the kernel, however
how I can analyze the obtained vmcores from previous kernels?
To analyze the vmcore with "crash" I need a corresponding mapfile for
that kernel versions.
Or there is not a big sense to do this?

It says something like this:

```
RIP [<ffffff802451ae>] rt_check_expire +0xea/0x23b  
Kernel panic - not syncing: Fatal exception
```

I'm not sure that this will be helpful without analyzing of kernel dump.

Thanks a lot!
