I do not know if anyone has come across this issue,in using VirtualBox and VMware with OpenVZ,using newer OVZ kernels for RHEL 5.(stab85)

The OS is Oracle Enterprise,upgraded to 5.5,but I do not think this is OS specific,as both VMware and VirtualBox run perfect on any OVZ Fedora server.(12 - 13)

The issue is in building the network device module in both software.(fails)

Installed the usual requirements.(source,headers,devel for OVZ kernel revision level for RHEL5)

Kernel module builds okay in both,but build fails at "netdrv module".

The software versions I used was VMware 2.x and VirtualBox 3.28.x.

I even backtracked to VMware 1.0.

As I stated,both build perfect on Fedora,using OVZ kernel source.

I have both Oracle 6 and RHEL6 DVD's to upgrade to,but at this time,I prefer Fedora servers.

Thought I would pass this along,as I have not found a specific post on the subject.
