+               Block device I/O bandwidth controller
+
+----------------------------------------------------------------------
+1. DESCRIPTION
+
+This controller allows to limit the I/O bandwidth of specific block devices for
+specific process containers (cgroups) imposing additional delays on I/O
+requests for those processes that exceed the limits defined in the control
+group filesystem.
+
+Bandwidth limiting rules offer better control over QoS with respect to priority
+or weight-based solutions that only give information about applications'
+relative performance requirements. Nevertheless, priority based solutions are
+affected by performance bursts, when only low-priority requests are submitted
+to a general purpose resource dispatcher.
+
+The goal of the I/O bandwidth controller is to improve performance
+predictability and provide performance isolation of different control groups
+sharing the same block devices.
+
+NOTE #1: If you're looking for a way to improve the overall throughput of the
+system probably you should use a different solution.
+
+NOTE #2: The current implementation does not guarantee minimum bandwidth
+levels, the QoS is implemented only slowing down I/O "traffic" that exceeds the
+limits specified by the user; minimum I/O rate thresholds are supposed to be
+guaranteed if the user configures a proper I/O bandwidth partitioning of the
+block devices shared among the different cgroups (theoretically if the sum of
A new I/O bandwidth limitation rule is described using the file
`blockio.bandwidth`. The same file can be used to set multiple rules for different block devices relative to the same cgroup.

2.1. Configure I/O bandwidth limiting rules

The syntax to configure a limiting rule is the following:

```
# /bin/echo DEV:BW:STRATEGY:BUCKET_SIZE > CGROUP/blockio.bandwidth
```

- DEV is the name of the device the limiting rule is applied to.
- BW is the maximum I/O bandwidth on DEV allowed by CGROUP; bandwidth must be expressed in bytes/s. A generic I/O bandwidth limiting rule for a block device DEV can be removed setting the BW value to 0.
- STRATEGY is the throttling strategy used to throttle the applications' I/O requests from/to device DEV. At the moment two different strategies can be used:
  
  0 = leaky bucket: the controller accepts at most B bytes (B = BW * time); further I/O requests are delayed scheduling a timeout for the tasks that made those requests.

```
 DIFFERENT I/O FLOW
 | |
 | v |
 | v
| v
```

  
  1 = token bucket: BW tokens are added to the bucket every seconds; the bucket can hold at the most BUCKET_SIZE tokens; I/O requests are accepted if there are available tokens in the bucket; when

```
 SMOOTHED I/O FLOW
  
  / leaky-bucket
  
  ---
  
  v
```

  
  1

---
a request of N bytes arrives N tokens are removed from the bucket; if fewer than N tokens are available the request is delayed until a sufficient amount of token is available in the bucket.

Tokens (I/O rate)

```plaintext
  o  o  o
  \ / | Bucket size (burst limit)
  \ooo/ |
  ---- <---'
   \o o
   |oooo
   Incoming --->|---| Conforming
     I/O     |oo   I/O
     requests -->|---> requests
      |
      ---->|```

Leaky bucket is more precise than token bucket to respect the bandwidth limits, because bursty workloads are always smoothed. Token bucket, instead, allows a small irregularity degree in the I/O flows (burst limit), and, for this, it is better in terms of efficiency (bursty workloads are not smoothed when there are sufficient tokens in the bucket).

--- BUCKET_SIZE is used only with token bucket (STRATEGY == 1) and defines the size of the bucket in bytes.

--- CGROUP is the name of the limited process container.

Also the following syntaxes are allowed:

- remove an I/O bandwidth limiting rule
  ```
  # /bin/echo DEV:0 > CGROUP/blockio.bandwidth
  ```

- configure a limiting rule using leaky bucket throttling (ignore bucket size):
  ```
  # /bin/echo DEV:BW:0 > CGROUP/blockio.bandwidth
  ```

2.2. Show I/O bandwidth limiting rules

All the defined rules and statistics for a specific cgroup can be shown reading the file blockio.bandwidth. The following syntax is used:

```bash
$ cat CGROUP/blockio.bandwidth
```

MAJOR MINOR BW STRATEGY LEAKY_STAT BUCKET_SIZE BUCKET_FILL TIME_DELTA

MAJOR is the major device number of DEV (defined above)
MINOR is the minor device number of DEV (defined above)

- BW, STRATEGY and BUCKET_SIZE are the same parameters defined above

- LEAKY_STAT is the amount of bytes currently allowed by the I/O bandwidth controller (only used with leaky bucket strategy - STRATEGY == 0)

- BUCKET_FILL represents the amount of tokens present in the bucket (only used with token bucket strategy - STRATEGY == 1)

- TIME_DELTA can be one of the following:
  - the amount of jiffies elapsed from the last I/O request (token bucket)
  - the amount of jiffies during which the bytes given by LEAKY_STAT have been accumulated (leaky bucket)

Multiple per-block device rules are reported in multiple rows

(DEVi, i = 1 .. n):
+ $ cat CGROUP/blockio.bandwidth
+
+ MAJOR1 MINOR1 BW1 STRATEGY1 LEAKY_STAT1 BUCKET_SIZE1 BUCKET_FILL1 TIME_DELTA1
+ MAJOR1 MINOR1 BW2 STRATEGY2 LEAKY_STAT2 BUCKET_SIZE2 BUCKET_FILL2 TIME_DELTA2
+ ...
+ MAJORn MINORn BWn STRATEGYn LEAKY_STATn BUCKET_SIZEn BUCKET_FILLn TIME_DELTAAn
+

2.3 Configure I/O operations/sec limiting rules
+
+ The syntax to limit I/O operations/sec is the following:
+ 
+ # /bin/echo DEV:IOPS > CGROUP/blockio.iops
+
+ DEV is the name of the device the limiting rule is applied to.
+
+ IOPS is the number of the maximum I/O operations per second that can be issued on device DEV by the tasks belonging to cgroup CGROUP. The I/O operations limit can be removed setting IOPS to 0.
+

2.4 Show I/O operations/sec limiting rules
+
+ The I/O operations limits and statistics for a specific cgroup can be shown reading the file blockio.ops. The following syntax is used:
+
+$ cat CGROUP/blockio.iops
+MAJOR MINOR IOPS IOPS_STAT TIME_DELTA
+
MAJOR is the major device number of DEV (defined above)

MINOR is the minor device number of DEV (defined above)

IOPS is the I/O operations/sec limit

IOPS_STAT is the number of I/O operations accumulated by the iops counter

TIME_DELTA can be one of the following:
- the amount of jiffies during which the number of I/O operations reported in
  IOPS_STAT have been accumulated

Multiple per-block device rules are reported in multiple rows

(DEVI, i = 1 .. n):

$ cat CGROUP/blockio.bandwidth

MAJOR1 MINOR1 IOPS1 IOPS_STAT1 TIME_DELTA1
MAJOR2 MINOR2 IOPS2 IOPS_STAT2 TIME_DELTA2
...
MAJORn MINORn IOPSn IOPS_STATn TIME_DELTAn

2.5. Examples

* Mount the cgroup filesystem (blockio subsystem):
  # mkdir /mnt/cgroup
  # mount -t cgroup -oblockio blockio /mnt/cgroup

* Instantiate the new cgroup "foo":
  # mkdir /mnt/cgroup/foo
  --> the cgroup foo has been created

* Add the current shell process to the cgroup "foo":
  # /bin/echo $$ > /mnt/cgroup/foo/tasks
  --> the current shell has been added to the cgroup "foo"

* Give maximum 1MiB/s of I/O bandwidth on /dev/sda for the cgroup "foo", using
  leaky bucket throttling strategy:
  # /bin/echo /dev/sda:$((1024 * 1024)):0:0 > /mnt/cgroup/foo/blockio.bandwidth
  # sh
  --> the subshell 'sh' is running in cgroup "foo" and it can use a maximum I/O
      bandwidth of 1MiB/s on /dev/sda

* Give maximum 8MiB/s of I/O bandwidth on /dev/sdb for the cgroup "foo", using
  token bucket throttling strategy, bucket size = 8MiB:
  # /bin/echo /dev/sdb:$((8 * 1024 * 1024)):1:$((8 * 1024 * 1024)) > /mnt/cgroup/foo/blockio.bandwidth
  # sh
the subshell 'sh' is running in cgroup "foo" and it can use a maximum I/O bandwidth of 1MiB/s on /dev/sda (controlled by leaky bucket throttling) and 8MiB/s on /dev/sdb (controlled by token bucket throttling)

- Run a benchmark doing I/O on /dev/sda and /dev/sdb; I/O limits and usage defined for cgroup "foo" can be shown as following:
  - # cat /mnt/cgroup/foo/blockio.bandwidth
  - 8 16 8388608 1 0 8388608 -522560 48
  - 8 0 1048576 0 737280 0 0 216

- Extend the maximum I/O bandwidth for the cgroup "foo" to 16MiB/s on /dev/sda:
  - # /bin/echo /dev/sda:$((16 * 1024 * 1024)):0:0 > /mnt/cgroup/foo/blockio.bandwidth
  - # cat /mnt/cgroup/foo/blockio.bandwidth
  - 8 16 8388608 1 0 8388608 -84432 206436
  - 8 0 16777216 0 0 0 0 15212

- Remove limiting rule on /dev/sdb for cgroup "foo":
  - # /bin/echo /dev/sdb:0:0:0 > /mnt/cgroup/foo/blockio.bandwidth
  - # cat /mnt/cgroup/foo/blockio.bandwidth
  - 8 0 16777216 0 0 0 0 110388

- Set a maximum of 100 I/O operations/sec to /dev/sdc for cgroup "foo":
  - # /bin/echo /dev/sdc:100 > /mnt/cgroup/foo/blockio.iops
  - # cat /mnt/cgroup/foo/blockio.iops
  - 8 32 100 0 232268

- Remove limiting rule for I/O operations from /dev/sdc for cgroup "foo":
  - # /bin/echo /dev/sdc:0 > /mnt/cgroup/foo/blockio.iops

3. ADVANTAGES OF PROVIDING THIS FEATURE

- Allow I/O traffic shaping for block device shared among different cgroups
- Improve I/O performance predictability on block devices shared between different cgroups
- Limiting rules do not depend of the particular I/O scheduler (anticipatory, deadline, CFQ, noop) and/or the type of the underlying block devices
- The bandwidth limitations are guaranteed both for synchronous and asynchronous operations, even the I/O passing through the page cache or buffers and not only direct I/O (see below for details)
- It is possible to implement a simple user-space application to dynamically adjust the I/O workload of different process containers at run-time, according to the particular users' requirements and applications' performance constraints
- It is even possible to implement event-based performance throttling mechanisms; for example the same user-space application could actively throttle the I/O bandwidth to reduce power consumption when the battery of a
mobile device is running low (power throttling) or when the temperature of a
card is too high (thermal throttling)

4. DESIGN

The I/O throttling is performed imposing an explicit timeout, via
schedule_timeout_killable() on the processes that exceed the I/O bandwidth
dedicated to the cgroup they belong to. I/O accounting happens per cgroup.

It just works as expected for read operations: the real I/O activity is reduced
synchronously according to the defined limitations.

Write operations, instead, are modeled depending of the dirty pages ratio
(write throttling in memory), since the writes to the real block devices are
processed asynchronously by different kernel threads (pdflush). However, the
dirty pages ratio is directly proportional to the actual I/O that will be
performed on the real block device. So, due to the asynchronous transfers
through the page cache, the I/O throttling in memory can be considered a form
of anticipatory throttling to the underlying block devices.

Multiple re-writes in already dirtied page cache areas are not considered for
accounting the I/O activity. This is valid for multiple re-reads of pages
already present in the page cache as well.

This means that a process that re-writes and/or re-reads multiple times the
same blocks in a file (without re-creating it by truncate(), ftruncate(),
creat(), etc.) is affected by the I/O limitations only for the actual I/O
performed to (or from) the underlying block devices.

Multiple rules for different block devices are stored in a linked list, using
the dev_t number of each block device as key to uniquely identify each element
of the list. RCU synchronization is used to protect the whole list structure,
since the elements in the list are not supposed to change frequently (they
change only when a new rule is defined or an old rule is removed or updated),
while the reads in the list occur at each operation that generates I/O. This
allows to provide zero overhead for cgroups that do not use any limitation.

WARNING: per-block device limiting rules always refer to the dev_t device
number. If a block device is unplugged (i.e. a USB device) the limiting rules
defined for that device persist and they are still valid if a new device is
plugged in the system and it uses the same major and minor numbers.

NOTE: explicit sleeps are *not* imposed on tasks doing asynchronous I/O (AIO)
operations; AIO throttling is performed returning -EAGAIN from sys_io_submit().
Userspace applications must be able to handle this error code opportunely.
+5. TODO
+
+* Think an alternative design for general purpose usage; special purpose usage
+ right now is restricted to improve I/O performance predictability and
+ evaluate more precise response timings for applications doing I/O. To a large
+ degree the block I/O bandwidth controller should implement a more complex
+ logic to better evaluate real I/O operations cost, depending also on the
+ particular block device profile (i.e. USB stick, optical drive, hard disk,
+ etc.). This would also allow to appropriately account I/O cost for seeky
+ workloads, respect to large stream workloads. Instead of looking at the
+ request stream and try to predict how expensive the I/O cost will be, a
+ totally different approach could be to collect request timings (start time /
+ elapsed time) and based on collected informations, try to estimate the I/O
+ cost and usage (idea proposed by Andrew Morton <akpm@linux-foundation.org>).
