Most - but not *all*.

Actually I quite agree with Linus - unwinder is just a pain,

which is the more unreliable then a plain call trace.

Plain call trace has one advantage - it prints more then needed

but it always print the required and clear info.

unwinder goes totally mad when something serious happens like stack overflows/corruption or other bad thing. 2 my cents.

no. bogus entries don't make call trace irrelevant.

And it is very easy to find relevant call trace entries in std output -

call trace should always be correct from the top and from the bottom,

all other entries are checked by eip following the calls.
