So, I manually loaded ip_conntrack and then manually loaded vzctl (both with insmod and the full path) and it works now.

Why the system couldn't figure it out on its own, I'm not sure.

Forgive my ignorance on module management... I used to be better at it a few years ago... but have gotten rusty. So, I'm guessing there is something I can add to my /etc/modprobe.conf to make it more intelligent?

I already have:

Quote:options ip_conntrack ip_conntrack_enable_ve0=1
