This is only the slave database server. The master server is dedicated to mysql. This is the only server that is able to handle that load. At the moment the system handles all of these VPSs in its host system. To have a more secure system I think it would be wise to split the server into security units. That way an attack to the testing system is only local to that system and NO exploit on the testing system is able to delete the database server because it is in an other VPS.

I really hope someone can give me some hints how to configure that host to have maximum performance and stability.

Bernhard
