cleavoy, OpenVZ works with VLANs.

I suppose you simply need to setup correct routing rules in host system. Something like:

```
# /sbin/ip r a 192.168.77.0/24 dev eth0.0 src 192.168.77.2
```

Also according to 'man vz', this option should also help you:

Quote:

Network interface parameters

VE_ROUTE_SRC_DEV="device"

This parameter specifies the network device name which ip address will used for source ip. If on HN configured > 1 network interfaces and needed to specify the source ip address, set corresponding device. By default takes the first in network device list.

this parameter is used in /usr/lib/vzctl/scripts/vps-net_add scripts.
