I have already found the same quote in the man-pages.

It states that : by default all iptables modules that are loaded in the host system are accessible inside a VE.

As mentioned in my first post, I already have iptables running on the host (including NAT), why I assumes that all necessary kernel modules should be loaded.

I have tried to stop and restart the VPS so the iptables modules is loaded before VPS start.

So i'm still interesting in any hints.

Most post (and wiki documentation) is about iptables on the host handling VPS access - and I have it all up and running.

But I can't run iptables inside the VPS.

Is there any non standard modules required ?

Regards Thomas
