Subject: Double carriage return within ftp from a VZ preventing logins

We've encountered a bizarre problem attempting to ftp from a virtual box where typing the username issues a double carriage return even though a single one is pressed. Consequently the receiving ftp server treats the second carriage return as a null password and therefore causes the login to fail. The problem does not occur on the physical box, only the virtual machines

The command line workaround is to type user username password from within the ftp session i.e username and pass on the same line.

Unfortunately what led us to use ftp and not scp is that the vz server needs to run a closed source java program which ftps out and is also hitting the double carriage return / login failed problem

I realise this is pretty obscure but if anyone has any ideas it would be appreciated
