Ok, thanks a lot for your answer, I will try to make myself more clear,

On the OpenVZ kernel, I have created some containers. When the computer boots, I am not in any container, but I can enter in anyone of them by entering the command `vzctl enter 3` for example.

So, if there are a lot of users in this computer, each of them can access to any container.

I just would like to know if there is a way to avoid it, to force to enter a password to access the container. Each user would have his own container.

Then, when the computer boots, is there a way to ask to the user in which container he wants to log on (which may include the physical machine itself)?

I hope it is better explained now, but anyway don't hesitate to tell me if it is not the case

Thanks for you help!
