---

does it hit privvmpages limit even when run in the host?

it should perfectly run and there should be no much difference in this regard between OVZ and RHEL4 kernel.

the only difference can be due to 4GB split option, but it should affect only RHEL4-enterprise kernel, though you are running SMP (according to the post).

So, maybe you can provide some hint on how it fails? is there something in dmesg? mmm... maybe it hits not only the privvmpages?

does your application require much time to fail? if not, you can try to strace it and find out on which operation it fails...
