The uname script only works for things that actually call /bin/uname. At the moment, I've replaced /bin/bash with a slightly modified setarch that setarch's then runs the real bash. Is there a bug open or version-eta for the vzctl setarch feature?

Something interesting...

If I do:

setarch i686 vzctl start 200

then SSH into the VPS and do uname -ar, it will say i686. If I do vzctl enter 200, it'll say x86_64.

So for now, a "cleaner" solution seems to be doing setarch to vzctl.
