I did a quick test with this kernel on my RHEL6 desktop (one reboot). First of all: I had no problems when I upgrade this destop machine from 2.6.32-44.el6 to 2.6.32-71.el6.

Booting with 042test003.1.x86_64 the following happens:

- udev error message in 60-vzctl.rules while booting (not critical I think)
- GUI doesn't start, X server can't load the proprietary nvidia driver (256.53, reinstall may fix this problem)
- I try to mount a remote samba share (on HN) as root, (mount -t cifs ...) but no luck:
mount error(1): Operation not permitted

With smbclient, I just wanted to check that this problem is still exist or not:
bugzilla.openvz.org/show_bug.cgi?id=1706

Server side:
Unfortunately the lp driver (CONFIG_PRINTER) was removed from RHEL6 kernels, and the RHEL6 based openvz kernel also doesn't include this. However I use the lp driver, so from now I should rebuild kernels with (CONFIG_PRINTER=m) for my (almost all) future servers. At moment I have no time to do so, therefore I can't test this kernel on my local server.
