I assume all 5 IPs are in the same subnet? Bind the first IP to the hardware node's eth0 as you would normally do, that's it. No need for aliases, no need for any kind of manual traffic forwarding.

Afterwards assign other 4 IP's to specific virtual machines trough openvz scripts. They'll just "magically" work. You can either assign one or more of the IPs to a single virtual machine.

It's really that simple.
