Hi!
I hate to start a new thread...but the way this thing is organized is not good. I found one "solved" thread with no followup or solution posted.

Ok..first I should say I am far from a newbie at this.
I just installed Cpanel on a Fed5 complete install (mine)
which basically means it has almost everything you would expect..gcc, perl expect, Update ran...YUm installed..even the infamous perl module that has a habit of going missing...
Tie::IxHash

I thought I could trust the install logs (basically useless)
and have logged all the putty output and are going to comb through it for more clues.

Sadly..this attempt #6 or #7...I lose track. As I write this..I'm trying on Fed 4 complete..as above.

I even tried the perl install they provide first..even worse than without.

I started out with Centos 4.3...and this install on fed 5 seems to be a little better.

As I prepare to comb the logs...any clues right off the bat?

Alright...exact same problems. WHM is locked into the setup cycle..I've done ./upcp, of course..little improvement.

At least the news works on FC4 and FC5..even that does not work on Centos4.3.

Let's go log combing!

Thanks

Bryon
