Subject: [PATCH] cgroups: implement device whitelist lsm (v3)
Posted by serue on Thu, 13 Mar 2008 14:41:42 GMT
View Forum Message <> Reply to Message

Implement a cgroup using the LSM interface to enforce open and mknod
on device files.

This implements a simple device access whitelist. A whitelist entry
has 4 fields. 'type' is a (all), c (char), or b (block). 'all' means it
applies to all types, all major numbers, and all minor numbers. Major and
minor are obvious. Access is a composition of r (read), w (write), and
m (mknod).

The root devcgroup starts with rwm to 'all'. A child devcg gets a copy
of the parent. Admins can then add and remove devices to the whitelist.
Once CAP_HOST_ADMIN is introduced it will be needed to add entries as
well or remove entries from another cgroup, though just CAP_SYS_ADMIN
will suffice to remove entries for your own group.

An entry is added by doing "echo <type> <maj> <min> <access>" > devcg.allow,
for instance:

echo b 7 0 mrw > /cgroups/1/devcg.allow

An entry is removed by doing likewise into devcg.deny. Since this is a
pure whitelist, not acls, you can only remove entries which exist in the
whitelist. You must explicitly

echo a 0 0 mrw > /cgroups/1/devcg.deny

to remove the "allow all" entry which is automatically inherited from
the root cgroup.

While composing this with the ns_cgroup may seem logical, it is not
the right thing to do, because updates to /cg/cg1/devcg.deny are
not reflected in /cg/cg1/cg2/devcg.allow.

A task may only be moved to another devcgroup if it is moving to
a direct descendent of its current devcgroup.

CAP_NS_OVERRIDE is defined as the capability needed to cross namespaces.
A task needs both CAP_NS_OVERRIDE and CAP_SYS_ADMIN to create a new
devcgroup, update a devcgroup's access, or move a task to a new
devcgroup.

CONFIG_COMMONCAP is defined whenever security/commoncap.c should
be compiled, so that the decision of whether to show the option
for FILE_CAPABILITIES can be a bit cleaner.

Changelog:
 Mar 13 2008: move the dev_cgroup support into
  capability hooks instead of having it
  as a separate security module.
  Support root_plug with devcg.
  Note that due to this change, devcg will
  not be enforcing if the dummy module is
  loaded, or if selinux is loaded without
  capabilities.
 Mar 12 2008: allow dev_cgroup lsm to be used when
  SECURITY=n, and allow stacking with SELinux
  and Smack.  Don't work too hard in Kconfig
  to prevent a warning when smack+devcg are
  both compiled in, worry about that later.

Actually, I'm not sure that the LSM approach in general is best here.

The LSM model is that standard DAC logic lives in the core kernel, and that extended security logic (e.g. MAC) is called after DAC via hooks. cgroups has introduced new security logic of its own, which is arguably "standard DAC" when cgroups is enabled.

I can understand Greg not wanting this security logic in the core kernel, but it is specific to cgroups (which itself is security model agnostic) and does not stand alone as a distinct security framework.

The fact that all existing LSMs need to invoke exactly the same code is an indicator that it doesn't belong in LSM.

Moving this logic into LSM means that instead of the cgroups security logic being called from one place in the main kernel (where cgroups lives), it must be called identically from each LSM (none of which are even aware of cgroups), which I think is pretty obviously the wrong solution.

This is baggage which comes with cgroups -- please don't push it into LSM to try and hide that.

I agree with the above, and would further note that I would expect the
SELinux solution to the problem would be done not by stacking with or
calling this device whitelist lsm but instead by introducing the ability
to bind security labels to devices within the kernel (independent of the
particular device node(s) in the filesystem used to access that device)
and applying permission checks on those device labels when processes
attempt to create or access those devices (again independent of the
particular device node used to access them). That keeps the policy
integrated and analyzable and avoids an external dependency.

I completely disagree. We have two separate frameworks in the kernel, one to enforce generic additional security stuff, and one to track tasks. When I need a feature which tracks tasks to do some security tasks, it seems obvious that I would use both, just like to enforce a certain type of MAC I end up using both netfilter and LSM through selinux.

> > The fact that all existing LSMs need to invoke exactly the same code is an

No, that's like saying capabilities don't belong in LSM because all LSMS need to invoke it the same way. What it is an indicator of is that there are (not-quite-)orthogonal pieces of security which users might want to use together.

As I told stephen I hope to provide the enhanced selinux support for devices, and at that point perhaps you won't want to support SELINUX+CGROUPS_DEV anymore.

Now that's just my opinion and it doesn't count for much. I'll do whatever everyone can agree on, but will wait for Paul's opinion about adding cgroup hooks next to the two security hooks.

Depends on whether you think LSM hooks are like netfilter hooks (i.e.
fine for each module to just implement a few here and there, then
combine resulting modules), or whether they are about implementing
complete security models (ala SELinux or Smack). As they currently
exist, they aren't very well suited to the former - they impose a cost
on all hooked operations in order to hook any at all, as has been a
concern for your device controller.

Likely not a popular view, but capabilities don't belong in LSM. Look
at them: the capability state is still directly embedded in the
relevant kernel data structures, various bits of capability specific
logic and interfaces remain in the core kernel, they don't present a
complete security model (just an auxiliary to some other model like DAC
or Smack for privilege purposes), they use only a small subset of the
hooks, they force LSM to violate its usual restrictive-only paradigm to
support capable(), CONFIG_SECURITY=n still has to invoke the capability
functions, and all of the other LSMs do need to call it the same way to
keep Linux working as expected for applications and users.

The original promise was that LSM would allow kernels to be built that
shed capabilities altogether, but in practice no one seems to do that as
both users and applications expect them to exist in Linux. In fact, the
possibility of not having capabilities present has caused problems that
have led to the dummy module being turned more and more into a clone of
the capabilities module (actually managing and testing the capability
bits rather than just uid == 0 as originally).

So I wouldn't point to capabilities as a counter example to James' point
- they are actually a supporting example.

I don't intend that Smack be thought of as a complete security model.
Smack implements Mandatory Access Control, but leaves the privilege
mechanism (root and/or capabilities) to the whims of others. Similarly
Smack does not do DAC (unlike SELinux with MCS) although "owned rules"
has been proposed as an additional feature. I certainly wouldn't
want every new facility that comes in to require multiple versions
that depend on the other LSMs involved. It's true that today's LSM is
optimized for the only LSM that existed a year ago, and that was a
monolythic security model.

I share this view, which add credibility to the claim that it's
not popular. (smiley)

> Look
> at them:  the capability state is still directly embedded in the

> logic and interfaces remain in the core kernel,

It does seem as if a separate Linux Privilege Module framework
might be a better scheme. It would be very easy to pull out, and
simple to create the obvious LPMs:

- Traditional root
  hooks look like "return (euid == 0) ? 0 : -EACCES;"
- No access check at all
  hooks look like "return 0;"
- Root or capabilities
  hooks look like "return (euid == 0 || capable(xxx)) ? 0 : -EACCES;"
- Pure capabilities

hooks look like "return capable(xxx) ? 0 : -EACCES;"

> they don't present a
> complete security model (just an auxiliary to some other model like DAC

> keep Linux working as expected for applications and users.

Plus, if SELinux wants to abandon capabilities they can add thier own
scheme or insist the user use the noop LPM and do whatever they like
in the LSM. Smack has no intention of mucking with the privilege
mechanism, and will happily go along with whatever the rest of the
system wants to use, although the noop LSM seems a bit pointless in
that case.

> The original promise was that LSM would allow kernels to be built that
> shed capabilities altogether,

I don't remember that, but it's been a long time so it could be true.

> but in practice no one seems to do that as

This is why Smack is sticking to MAC rather than trying to be a
wholistic security policy mechanism. To quote the prophet, "God
created the world in 7 days, but then, He didn't have an install
base".

> So I wouldn't point to capabilities as a counter example to James' point
> - they are actually a supporting example.

In particular, capabilities are not an access control mechanism,
they are a privilege mechanism. A lot of discussion about LSM has
centered around the appropriate charactoristics of an LSM, and
these discussions always assume that the LSM in question is
exactly an access control mechanism. If we split the LSM into
a LACM for access control and an LPM for privilege management
maybe we can eliminate the most contentious issues.

Does anyone know why that would be stoopid before I whack out
patches?

Thank you.

By complete security model, I don't mean it has to be MAC+DAC
+privileges. Just that it does in fact implement a well formed security
model, not just an ad hoc set of stupid security tricks. Smack and

SELinux are examples of the former.

> > > > > The fact that all existing LSMs need to invoke exactly the same code is

"One of the explicit requirements to get LSM into the kernel was to have
the ability to make capabilities be a module.  This allows the embedded
people to completely remove capabilities, as they really want this.  I
don't think we can ignore this, no matter how much of a pain in the butt
it is :)" - Greg KH

Quoted from:
http://marc.info/?l=linux-security-module&m=99236500727804&w=2

Ironically, since that time, capabilities have doubled in size and still
can't be removed from the core kernel since LSM didn't push the state
into the security blobs.

If you do re-factor it in that manner, SELinux will have to register
under both schemes in order to preserve its current logic, of course.

And there are points of overlap between the two schemes even for
non-privilege-managing security modules (e.g. they both need hooks on
ptrace, inode_setxattr, etc).

Lastly, since LSM didn't really do the job of migrating the capability
state out of the core kernel data structures and fully encapsulating the
capability logic, you'd have to do that work too to do it right.

No I'd like to see those patches.  It would ideally allow LSM to become
*purely* restrictive and LPM to be purely empowering, presumably making
the resulting hook sets easier to review and maintain.  The LPM wouldn't
(I assume) gain any *new* hook points so we wouldn't be adding any new
places for hooks to be overriden by a rootkit.

I don't expect to put in any additional hooks points, although
it's safe to bet that someone will want to pretty quickly. What
I see as the big concern is our old friend the granularity question.
I can pretty well predict that we'll have quite a bruhaha over
whether each hook point should have it's own hook or if they should
be shared based on the privilege supported. For example, in namei.c
the function generic_permission() currently calls
capable(CAP_DAC_OVERRIDE). The privilege supported approach would
be to create a hook that gets used in many places that is a drop-in
replacement for that,

```
        if (capable(CAP_DAC_OVERRIDE))
becomes
        if (lpm_dac_override())
```

The alternative is to go the same route as the LSM, where it
becomes

```
        if (lpm_generic_permission_may_exec())
```

The former scheme is much easier to implement. It also would
mean that if would wanted to implement a finer granularity on
DAC overrides (e.g. CAP_DAC_READ, CAP_DAC_WRITE, CAP_DAC_EXECUTE)
you would have to introduce new hooks. That wouldn't be any worse

than today's situation where you would have to change the argument
passed to capable as far as the calling (e.g. generic_permission)
code is concerned, but it would mean updating all the LPMs. I
currently count 1084 calls to capable (sloppy grep method) and that's
way too many hooks in my mind. But, if there's anyone who thinks
that the way to go is for each existing capable call to be a hook,
feel free to make a convincing argument.

This should be fun.

nit:  I'd use priv_ rather than lpm_, just as we use security_ rather
than lsm_.

Do you plan to pass other arguments to the privilege hook call, like the
object?  If not, then there is no point in changing the capable call
sites at all - just change its implementation to invoke a priv_capable()
hook instead of a security_capable() hook.

Changing all of the call sites seems a bit prohibitive for an initial
implementation; rewiring the internals of capable() to use a new
privilege hook interface would be a lot simpler.

You also have to migrate the other security hooks presently used to
support capabilities to your privilege framework.

Maybe we need to seriously revisit this and perhaps rip capabilities
back out and put it always into the kernel if it's always a requirement.

Comments made 7 years ago might be totally wrong when we have now
learned how this all has worked out...

thanks,

greg k-h
