I downloaded http://download.openvz.org/template/precreated/contrib/centos-5-x86_64-default-5.4-20091022.tar.gz
and placed it in /vz/template/cache

then:
% vzctl create 103 --ostemplate centos-5-x86_64-default-5.4-20091022
Unable to get full ostemplate name for centos-5-x86_64-default-5.4-20091022
Creating container private area (centos-5-x86_64-default-5.4-20091022)
Performing postcreate actions
Container private area was created

what is that error: "Unable to get full ostemplate name"
will this affect administering the system at all?

Also, the hostnode is centos 5.3 should I use vzyum to update the CT or just use yum inside the container? What are the benefits of using vzyum over yum in the CT?

thanks

Hi,

Quote:
what is that error: "Unable to get full ostemplate name"
will this affect administering the system at all?

It doesn't affect administering the system.
The message means that the provided name of a cached template doesn't obey the internal form which is expected
(/usr/share/vzpkg/functions file; function ost2full())
But that's OK since you're using the precreated template.

Once the package has been dowloaded it may be installed into different VEs without downloading it once more.
