Subject: userns: targeted capabilities v5
Posted by serge on Thu, 17 Feb 2011 15:02:24 GMT
View Forum Message <> Reply to Message

Here is a repost of my previous user namespace patch, ported onto
last night's git head.

It fixes several things I was doing wrong in the last (v4)
posting, in particular:

1. don't set uts_ns->user_ns to current's when !CLONE_NEWUTS
2. add a ipc_ns->user_ns which owns ipc_ns, and use that to
   decide CAP_IPC_OWNER
3. fix logic flaw caused by bad parantheses
4. allow do_prlimit to current
5. don't always give root full privs to init_user_ns

The expected course of development for user namespaces is laid out
at https://wiki.ubuntu.com/UserNamespace. Bugs aside, this
patchset is supposed to not at all affect systems which are not
actively using user namespaces, and only restrict what tasks in
child user namespace can do. They begin to limit privilege to
a user namespace, so that root in a container cannot kill or
ptrace tasks in the parent user namespace, and can only get
world access rights to files. Since all files currently belong
to the initila user namespace, that means that child user
namespaces can only get world access rights to *all* files.
While this temporarily makes user namespaces bad for system
containers, it starts to get useful for some sandboxing.

I've run the 'runltplite.sh' with and without this patchset and
found no difference. So all in all, this is the first version
of this patchset for which I feel comfortable asking: please
consider applying.

thanks,
-serge

Subject: [PATCH 1/9] Add a user_namespace as creator/owner of uts_namespace
Posted by serge on Thu, 17 Feb 2011 15:02:57 GMT
View Forum Message <> Reply to Message

copy_process() handles CLONE_NEWUSER before the rest of the

namespaces. So in the case of clone(CLONE_NEWUSER|CLONE_NEWUTS)
the new uts namespace will have the new user namespace as its
owner. That is what we want, since we want root in that new
userns to be able to have privilege over it.

Changelog:
 Feb 15: don't set uts_ns->user_ns if we didn't create
  a new uts_ns.

Subject: [PATCH 2/9] security: Make capabilities relative to the user namespace.
Posted by serge on Thu, 17 Feb 2011 15:03:06 GMT
View Forum Message <> Reply to Message

- Introduce ns_capable to test for a capability in a non-default
  user namespace.
- Teach cap_capable to handle capabilities in a non-default
  user namespace.

The motivation is to get to the unprivileged creation of new
namespaces. It looks like this gets us 90% of the way there, with
only potential uid confusion issues left.

I still need to handle getting all caps after creation but otherwise I
think I have a good starter patch that achieves all of your goals.

Changelog:
 11/05/2010: [serge] add apparmor
 12/14/2010: [serge] fix capabilities to created user namespaces
 Without this, if user serge creates a user_ns, he won't have
 capabilities to the user_ns he created. THis is because we
 were first checking whether his effective caps had the caps
 he needed and returning -EPERM if not, and THEN checking whether
 he was the creator. Reverse those checks.
 12/16/2010: [serge] security_real_capable needs ns argument in !security case
 01/11/2011: [serge] add task_ns_capable helper
 01/11/2011: [serge] add nsown_capable() helper per Bastian Blank suggestion
 02/16/2011: [serge] fix a logic bug: the root user is always creator of
     init_user_ns, but should not always have capabilities to
     it! Fix the check in cap_capable().

Subject: [PATCH 4/9] allow killing tasks in your own or child userns
Posted by serge on Thu, 17 Feb 2011 15:03:25 GMT
View Forum Message <> Reply to Message

```
Changelog:
 Dec  8: Fixed bug in my check_kill_permission pointed out by
         Eric Biederman.
 Dec 13: Apply Eric's suggestion to pass target task into kill_ok_by_cred()
         for clarity
 Dec 31: address comment by Eric Biederman:
  don't need cred/tcred in check_kill_permission.
 Jan  1: use const cred struct.
 Jan 11: Per Bastian Blank's advice, clean up kill_ok_by_cred().
 Feb 16: kill_ok_by_cred: fix bad parentheses

Subject: [PATCH 5/9] Allow ptrace from non-init user namespaces
Posted by serge on Thu, 17 Feb 2011 15:03:33 GMT
View Forum Message <> Reply to Message

ptrace is allowed to tasks in the same user namespace according to
the usual rules (i.e. the same rules as for two tasks in the init
user namespace). ptrace is also allowed to a user namespace to
which the current task the has CAP_SYS_PTRACE capability.

Changelog:
 Dec 31: Address feedback by Eric:
  . Correct ptrace uid check
  . Rename may_ptrace_ns to ptrace_capable
  . Also fix the cap_ptrace checks.
 Jan 1: Use const cred struct
 Jan 11: use task_ns_capable() in place of ptrace_capable().

```

Subject: [PATCH 6/9] user namespaces: convert all capable checks in kernel/sys.c
Posted by serge on Thu, 17 Feb 2011 15:03:42 GMT
View Forum Message <> Reply to Message

This allows setuid/setgid in containers. It also fixes some
corner cases where kernel logic foregoes capability checks when
uids are equivalent. The latter will need to be done throughout
the whole kernel.

Changelog:
 Jan 11: Use nsown_capable() as suggested by Bastian Blank.
 Jan 11: Fix logic errors in uid checks pointed out by Bastian.
 Feb 15: allow prlimit to current (was regression in previous version)

Signed-off-by: Serge E. Hallyn <serge.hallyn@canonical.com>

Subject: [PATCH 8/9] user namespaces: convert several capable() calls
Posted by serge on Thu, 17 Feb 2011 15:03:56 GMT
View Forum Message <> Reply to Message

CAP_IPC_OWNER and CAP_IPC_LOCK can be checked against current_user_ns(),
because the resource comes from current's own ipc namespace.

setuid/setgid are to uids in own namespace, so again checks can be

against current_user_ns().

Changelog:
 Jan 11: Use task_ns_capable() in place of sched_capable().
 Jan 11: Use nsown_capable() as suggested by Bastian Blank.
 Jan 11: Clarify (hopefully) some logic in futex and sched.c
 Feb 15: use ns_capable for ipc, not nsown_capable

Subject: [PATCH 9/9] userns: check user namespace for task->file uid equivalence checks

Posted by serge on Thu, 17 Feb 2011 15:04:07 GMT
View Forum Message <> Reply to Message

Cheat for now and say all files belong to init_user_ns. Next
step will be to let superblocks belong to a user_ns, and derive
inode_userns(inode) from inode->i_sb->s_user_ns. Finally we'll
introduce more flexible arrangements.

Changelog:
Feb 15: make is_owner_or_cap take const struct inode

Seems like a nice feature to be developing.

I worry about the maturity of it all at this stage. How far along is
it *really*?

Is anyone else working with you on developing and reviewing this work?

This looks good. I am a little worried that a concept like
inode_user_ns will imply that there is only ever one.

However this looks like a good place to start and it will only
be strange filesystems that implement a notion of permissions
that is namespace aware so I don't expect the generic code
needs to handle that case other than allowing the permission checks
to be overridden.

Some nits below. But this generally looks good if a little bit all over
the map for a single patch.

Acked-by: "Eric W. Biederman" <ebiederm@xmission.com>

>   return -1;

Serge can we please modify the code to pass the ns down from
ipcget_public to ipcperms. It is passed in and dropping the value and
going back to current to get it just feels wrong.

Strictly speaking this code is correct but it requires an audit of all
of the callers to know that, which is unfortunate.

>   return ipcp;

Like the other ipc call can we please pass the ipc_ns into ipcctl_pre_down.

The code as constructed appears correct but because we are passing the
namespace into the caller of this function always using current to get
the ipc_ns seems confusing and unnecessary.

Except for the extra printk in sethostname this looks good.

Ouch! This new print statement could be really annoying if an
unprivileged user calls sethostname. Could you remove it?

I don't see how it can go wrong at the moment but
same_or_ancestore_user_ns is too permissive and potentially inefficient.
Can you please replace it with a simple user namespace equality check.

Eric

I have commented on this before but I took a good hard look this time,
and can comment more intelligently.

The cap_issubset check is for the case where we don't use the
CAP_SYS_PTRACE capability, as such is only valid in the same user
namespace. Furthermore capabilities really are not comparable between
different user namespaces. So can you please replace the
same_or_ancestor_user_ns with a simple namespace equality check.
Having the wrong logic in here will just be confusing in the future.

Also could you name tcred child_cread I think that would be clearer in
the test below.

> + goto out;
> + ret = -EPERM;
> +out:
>   rcu_read_unlock();
>   return ret;

I also find it strange that we allow CAP_SYS_PTRACE to allow us to
ptrace processes with more capabilities than ourselves. But that is an
entirely different issue.

I did a lot of the initial design and I have been reviewing as I have
time.

Andrew at a practical level we have to merge this incrementally.
Anything much bigger than Serge's current patchset will be too big to
review. The first really bit step is making capabilities local to the
user namespace, and that is what this patchset does along with using
that localness in some good places.

Eric

Thanks, Andrew. I'm not sure what definition of 'maturity' you were looking for here. If you meant completeness of the feature, it's definately not there. Of the goals for user namespaces sandboxing will be the quickest to mature. Completing that will largely be an exercise of running the breadth of the kernel looking for simple uid/gid comparisons and making them namespace aware.

The design has been meshed around (publicly) on and off for many years by eric and I. This particular patchset has gotten some great reviews by Eric Biederman and Bastian Blank (to who, unfortunately, to this day I cannot send a direct email - they're always bounced).

As Eric said, this feature will have to go in incrementally. Furthermore, each piece touches scary code so it's likely to go pretty slowly. My hope is less than a year for sandboxing, and two years for containers. It might go way faster, but experience tells me that's unlikely :)

thanks,
-serge

> same_or_ancestor_user_ns with a simple namespace equality check.
> Having the wrong logic in here will just be confusing in the future.

I see. You're right, what's there is conceptually not quite right.
So I think we can just do:

```
 if (current_user_ns() == tcred->user->userns) &&
     cap_issubset(child, current)
  goto out;
 if ns_capable(tcred->user->user_ns, CAP_SYS_PTRACE)
  goto out;
```

This suffices since
 root in an ancestor ns will have CAP_SYS_PTRACE
 the user who created the user_ns will have CAP_SYS_PTRACE

Any user in an ancestor ns who does not have CAP_SYS_PTRACE will
be denied.

> Also could you name tcred child_cread I think that would be clearer in
> the test below.

Yes, will do, that'll be clearer. Thanks.

> > + if (ns_capable(tcred->user->user_ns, CAP_SYS_PTRACE))

I concur. I'm pretty sure it must stay, but it does feel icky.

I'll send out a new version

thanks

Two icky-should-be-written-in-C macros which reference init_user_ns,
followed by the declaration of init_user_ns and its type. Declarations
which duplicate those in other header files. It's ripe for some
upcleaning, methinks?

Also, please ensure that the forward struct declarations are all at
top-of-file (as in include/linux/security.h). Otherwise we can end up
accumulating multiple forward declarations of the same thing in the one
file.

Actually it doesn't return true or false - it returns 1 or 0. Using a
`bool' return type would fix the comment :)

So delete the code? Or does the compiler warn? If so, it's pretty busted.

bool?

> +EXPORT_SYMBOL(is_owner_or_cap);

There's a fairly well adhered to convention that global symbols (and
often static symbols) have a prefix which identifies the subsystem to
which they belong. This patchset rather scorns that convention.

Most of these identifiers are pretty obviously from the capability
subsystem, but still...

Hmmm... A chunk of the contents of the cred struct are user-namespaced.
Could you add the user_namespace pointer to the cred struct and thus avoid
passing it as an argument to other things.

In fact, I think you probably have to do this so that cachefiles, for example,
can override the user namespace when it operates on behalf of a process that's
in another namespace.

In fact, looking later on in your patch, I see:

> - || (cap_capable(current, current_cred(), CAP_SETPCAP,
> + || (cap_capable(current, current_cred(),
> + current_cred()->user->user_ns, CAP_SETPCAP,

so the user_ns _is_ already available through the creds. So is there really a need to pass it as an argument to anything that already takes a cred?

> * @cred contains the credentials to use.
> + * @ns contains the user namespace we want the capability in
> * @cap contains the capability <include/linux/capability.h>.

That should be tabbed to match the lines either side.

Why is that last comment so? Why should the creating namespace sport all

possible capabilities? Do you have to have all capabilities available to you to be permitted create a new user namespace?

Also, would it be worth having a separate cap_ns_capable()? Wouldn't most calls to cap_capable() only be checking the caps granted in the current user namespace?

I guess we need to look at how to mix keys and namespaces again.

Possibly the trickiest problem with keys is how to upcall key construction to /sbin/request-key when the keys may be of a different user namespace.

It's not the creating namespace, but the creating user, which has all caps.

So for instance, if uid 500 in init_user_ns creates a namespace, then:
  a. uid 500 in init_user_ns has all caps to the child user_ns, so it can
     kill the tasks in the userns, clean up, etc.
  b. uid X in any other child user_ns has no caps to the child user_ns.
  c. root in init_user_ns has whatever capabilities are in his pE to the
     child user_ns. Again, this is so that the admin in any user_ns can
     clean up any messes made by users in his user_ns.

One of the goals of the user namespaces it to make it safe to allow
unprivileged users to create child user namespaces in which they have
targeted privilege. Anything which happens in that child user namespace
should be:

  a. constrained to resources which the user can control anyway
  b. able to be cleaned up by the user
  c. (especially) able to be cleaned up by the privileged user in the
     parent user_ns.

> Also, would it be worth having a separate cap_ns_capable()? Wouldn't most
> calls to cap_capable() only be checking the caps granted in the current user
> namespace?

Hm. There is nsown_capable() which is targeted to current_userns(), but
that still needs to enable the caps for the privileged ancestors as
described above.

thanks,
-serge

We may want to look at this again, but for now I think that would be a
safe enough default. Later, we'll probably want the user creating a
child_user_ns to allow his keys to be inherited by the child user_ns.
Though, as I type that, it seems to me that that'll just become a
maintenance pain, and it's just plain safer to have the user re-enter
his keys, sharing them over a file if needed.

I'm going to not consider the TPM at the moment :)

Serge short term this is where I think we need to add a check or two so
that keys only work in the init_user_ns. When the rest of the details
are sorted out we can open up the use of keys some more.

As the first stage of converting the network stack we added patches
that turned off everything in non init namespaces. Those patches
were trivial and easy to review, and it made the conversion process
a lot easier. I suspect for keys and possibly security modules and
anything else that does is related we want to turn off by default.

Then once the core of user namespaces is safe to unshare without
privilege we can come back and get the more difficult bits.

Eric

I'm not sure that's currently completely true. Key quota maintenance is

namespaced, and the key's owner UID/GID belong to that namespace, so that's okay, but:

(*) key_task_permission() does not distinguish UIDs and GIDs from different namespaces.

(*) A key can be referred to by its serial number, no matter whose namespace it is in, and will yield up its given UID/GID, even if these aren't actually meaningful in your namespace.

This means request_key() can successfully upcall at the moment.

I wonder if I should make the following changes:

(1) If the key and the accessor are in different user namespaces, then skip the UID and GID comparisons in key_task_permission(). That means that to be able to access the key you'd have to possess the key and the key would have to grant you Possessor access, or the key would have to grant you Other access.

(2) If the key and someone viewing the key description are in different namespaces, then indicate that the UID and the GID are -1, irrespective of the actual values.

(3) When an upcall is attempting to instantiate a key, it is allowed to access the keys of requestor using the requestor's credentials (UID, GID, groups, security label). Ensure that this will be done in the requestor's user namespace.

Nothing should need to be done here, since search_process_keyrings() switches to the requestor's creds.

Oh, and are security labels user-namespaced?

That depends what you mean by 'allow his keys to be inherited'. Do you mean copying all the creator's keys en mass? You may find all you need to do is to provide the new intended user with a new session keyring with a link back to the creator's session keyring.

> Though, as I type that, it seems to me that that'll just become a
> maintenance pain, and it's just plain safer to have the user re-enter

That would certainly be simpler.

> sharing them over a file if needed.

I'm not sure what you mean by that. Do you mean some sort of cred passing
similar to that that can be done over AF_UNIX sockets with fds?

> I'm going to not consider the TPM at the moment :)

I'm not sure the TPM is that much of a problem, assuming you're just referring
to its keystore capability...

Not at this time. The user namespace as currently merged is little more
than a place holder for a proper implementation. Serge is busily
fleshing out that proper implementation.

Until we reach the point where all checks that have historically been
"if (uid1 == uid2)" become "if ((uidns1 == uidns2) && (uid1 == uid2))"
there will be problems.

The security labels and probably lsm's in general need to be per user
namespace but we simply have not gotten that far. For the short term I
will be happy when we get a minimally usable user namespace.

Note also that when Eric brought this up at the LSM mini-conf two or three
years ago, there was pretty general, strong objection to the idea.

Like Eric says, I think that'll have to wait. In the meantime, isolating
user namespace sandboxes (or containers) using simple LSM configurations
is a very good idea.

Hmmm. task_cred_xxx() uses task->real_cred, which is correct for victim (the object), but normally you'd use task->cred for task (the subject). However, in this case, I think it's probably okay.

Subject: Re: [PATCH 1/9] Add a user_namespace as creator/owner of uts_namespace
Posted by David Howells on Wed, 23 Feb 2011 17:16:33 GMT
View Forum Message <> Reply to Message

Serge E. Hallyn <serge@hallyn.com> wrote:

> struct uts_namespace {
> struct kref kref;
> struct new_utsname name;
> + struct user_namespace *user_ns;
> };

If a uts_namespace belongs to a user_namespace, should CLONE_NEWUSER then imply CLONE_NEWUTS?

Or is uts_namespace::user_ns more an implication that the set of users in user_namespace are the only ones authorised to alter the uts data.

I presume that the uts_namespace of a process must be owned by one of the user_namespaces in the alternating inheritance chain of namespaces and their creators leading from current_user_ns() to init_user_ns.

With that in mind, looking at patch 3:

```
- if (!capable(CAP_SYS_ADMIN))
+ if (!ns_capable(current->nsproxy->uts_ns->user_ns, CAP_SYS_ADMIN))
```

what is it you're actually asking? I presume it's 'does this user have CAP_SYS_ADMIN capability over objects belonging to the uts_namespace's user_namespace?'

So, to look at the important bit of patch 2:

```
-int cap_capable(struct task_struct *tsk, const struct cred *cred, int cap,
-  int audit)
+int cap_capable(struct task_struct *tsk, const struct cred *cred,
+  struct user_namespace *targ_ns, int cap, int audit)
 {
- return cap_raised(cred->cap_effective, cap) ? 0 : -EPERM;
+ for (;;) {
+  /* The creator of the user namespace has all caps. */
+  if (targ_ns != &init_user_ns && targ_ns->creator == cred->user)
+   return 0;
+
+  /* Do we have the necessary capabilities? */
+  if (targ_ns == cred->user->user_ns)
+   return cap_raised(cred->cap_effective, cap) ? 0 : -EPERM;
+
+  /* Have we tried all of the parent namespaces? */
+  if (targ_ns == &init_user_ns)
+   return -EPERM;
+
+  /* If you have the capability in a parent user ns you have it
+   * in the over all children user namespaces as well, so see
+   * if this process has the capability in the parent user
+   * namespace.
+   */
+  targ_ns = targ_ns->creator->user_ns;
+ }
+
+ /* We never get here */
+ return -EPERM;
```

```
}
```

On entry, as we're called from ns_capable(), cred->user is the user that the current process is running as, and, as such, may be in a separate namespace from uts_namespace - which may itself be in a separate namespace from init_user_ns.

So, assume for the sake of argument that there are three user_namespaces along the chain from the calling process to the root, and that the uts_namespace belongs to the middle one.

```
 if (targ_ns != &init_user_ns && targ_ns->creator == cred->user)
  return 0;
```

Can never match because targ_ns->creator cannot be cred->user; even if the uts_namespace belongs to our namespace, given that the creator lies outside our namespace.

```
 if (targ_ns == cred->user->user_ns)
  return cap_raised(cred->cap_effective, cap) ? 0 : -EPERM;
```

Can only match if we are in the target user_namespace (ie. the one to which uts_namespace belongs), whether or not we have CAP_SYS_ADMIN.

Which means that unless the uts_namespace belongs to our user_namespace, we cannot change it. Is that correct?

So ns_capable() restricts you to only doing interesting things to objects that belong to a user_namespace if they are in your own user_namespace. Is that correct?

If that is so, is the loop required for ns_capable()?

Looking further at patch 2:

```
#define nsown_capable(cap) (ns_capable(current_user_ns(), (cap)))
```

Given what I've said above, I presume the loop isn't necessary here either.

I think you're using ns_capable() in two different ways:

(1) You're using it to see if a process has power over its descendents in a user_namespace that can be traced back to a clone() that it did with CLONE_NEWUSER.

    For example, automatically granting a process permission to kill

descendents in a namespace it created.

(2) You're using it to see if a process can access objects that might be
outside its own user_namespace.

For example, setting the hostname.

Is it worth giving two different interfaces to make this clearer (even if they
actually do the same thing)?

Sorry if this seems rambly, but I'm trying to get my head round your code.

I confess that I remain less well educated on namespaces than
I probably should be, but with what I do know it seems that the
relationships between user namespaces and LSMs are bound to be
strained from the beginning. Some LSMs (SELinux and Smack) are
providing similar sandbox capabilities to what you get from user
namespaces, but from different directions and with different
use cases.

Casey I won't argue about the possibility of things being strained, but
I think if we focus on the semantics and not on the end goal of exactly
how the pieces are to be used there can be some reasonable dialog.

>From 10,000 feet an user namespace represents one administrative domain.
uids, gids and other external tokens are all controlled by a single
group with a single security policy. In that single administrative
domain things like nfs are expected to work without translating uids and
gids. Before the implementation of user namespaces a single kernel
could not even express the ability of dealing with multiple user
namespaces simultaneously (nfs has usually punted and said despite being
multiple machines you still have to be in the same administrative domain
so the same user identifiers can be used throughout).

>From that principle we have the concept that use assigned/visible
identifiers uid, gid, capabilities, security keys?, security labels?
logically belong to the user namespace.

Which means in implementing there are two pieces of work in implementing
the user namespace.

- Find all of the interesting comparisons and change them from
  "if (id == id)" to "if (userns == userns) && (id == id)".

- Potentially define and handle what happens when you mix user
  namespaces.

I think for the first round of this we simply want to define lsms
and the user namespace as not mixing or the lsm interfaces only being
visible if you are in the initial user namespace. Thus reserving the
definition of what happens when you have lsms and multiple user
namespaces as something we can define later. I expect the proper
definition is something that would allow nested lsm policy.

Regardless. The namespaces are all about making the identifiers that
processes deal with local to the namespace, while the underlying object
manipulations should not care.

The big advantage of the user namespace is that it is the only way I can
see to get us out of the bind we are in with suid root executables,
where we can not enable new features to untrusted applications that can
change the environment for a suid root executable, because it might
confuse those suid root executables to misusing their power. Once
inside a user namespace nothing has dangerous powers because even a
root owned process with a full set of capabilities is less powerful than
a guest user outside of the namespace. No process having dangerous
powers allows us to enable unsharing of other namespaces and potentially
other things that today are restricted with capabilities only because
they can be used to confuse a privileged executable to do something
malicious.

So we have the nested stack of:
user_ns3->creator->user_ns == user_ns2
user_ns2->creator->user_ns == &init_user_ns
uts_ns2->user_ns == user_ns2

>
>   if (targ_ns != &init_user_ns && targ_ns->creator == cred->user)
>   return 0;
>
> Can never match because targ_ns->creator cannot be cred->user; even if the
> uts_namespace belongs to our namespace, given that the creator lies outside
> our namespace.

Initially we come in with targ_ns == user_ns2 and cred->user->user_ns in
one of (user_ns3, user_ns2, or &init_user_ns).

targ_ns takes on values user_ns2 and &init_user_ns.

So when targ_ns becomes &init_user_ns. If the user in question is
uts_ns2->user_ns->creator. This check will indeed match.

>   if (targ_ns == cred->user->user_ns)
>   return cap_raised(cred->cap_effective, cap) ? 0 : -EPERM;
>
> Can only match if we are in the target user_namespace (ie. the one to which
> uts_namespace belongs), whether or not we have CAP_SYS_ADMIN.

As before targ_ns takes on values of user_ns2 and &init_user_ns.

Which means this check will match if we have CAP_SYS_ADMIN in
&init_user_ns or in user_ns2.

> Which means that unless the uts_namespace belongs to our user_namespace, we
> cannot change it. Is that correct?

No. If you are root in a parent namespace you can also change it.

> So ns_capable() restricts you to only doing interesting things to objects that

No. Root outside your user namespace is also allowed to do interesting
things.

I am all for making that loop a little clearer, because it is something
you have to pause and think about to understand but so far I don't think
the loop is wrong, and it is simple.

I'm sure that there will be cases where they will work together
like horses in a troika. Making sensible semantics for the interactions
is key, and it is entirely possible that in some cases a comparison
of semantics and behaviors will lead an end user to chose either an
LSM or namespaces over the combination. Just like I expect that even
when we allow multiple LSMs the SELinux and Smack combination will be
rare among the sane.

But surely, by definition, if you're a user in this namespace, you can't also
be root in a parent namespace...

For the case I worked through current_user() is a member of current_user_ns()
and can't also be a member of its parent, grandparent, etc. - or can it?

To be clear the case you looked at was:

> - if (!capable(CAP_SYS_ADMIN))
> + if (!ns_capable(current->nsproxy->uts_ns->user_ns, CAP_SYS_ADMIN))
>
> what is it you're actually asking? I presume it's 'does this user have
> CAP_SYS_ADMIN capability over objects belonging to the uts_namespace's

> user_namespace?'

Here "current->nsproxy->uts_ns->user_ns" (the target_ns value) is only
refers to the uts_ns we are talking about.

The user itself comes from current_user().

> For the case I worked through current_user() is a member of current_user_ns()
> and can't also be a member of its parent, grandparent, etc. - or can
> it?

Right now if you are looking at current_user() because of limitations in
the creation ordering I think you are correct.

However in the near term pile of changes to merge, are the syscalls for
joining an existing namespace. At which point there is no reason in
general to suppose the current limitations of creation apply.

Although it is conceivable that unshare of namespaces can also get you
to someplace similar to joining prexisting namespaces.

Eric

Thanks for the review, Andrew. Unfortunately this one is hard to turn
into a function beecause it uses security_real_capable(), which is
sometimes defined in security/security.c as a real function, and
other times as a static inline in include/linux/security.h. So
I'd have to #include security.h in capability.h, but security.h
already #includes capability.h.

All the other comments affect same_or_ancestor_user_ns(), which
following Eric's feedback is going away.

Is that simply true with everything (worth inlining) nowadays, or is
there a particular implicit hint to the compiler that'll make that
happen?

Not that I guess it's even particularly important in this case.

Subject: [PATCH] userns: ptrace: incorporate feedback from Eric
Posted by serge on Thu, 24 Feb 2011 00:49:01 GMT

View Forum Message <> Reply to Message

same_or_ancestore_user_ns() was not an appropriate check to
constrain cap_issubset. Rather, cap_issubset() only is
meaningful when both capsets are in the same user_ns.

We've basically stopped inlining things nowadays. gcc inlines
aggressively and sometimes we have to use noinline to stop it. Also,
modern gcc's like to ignore the inline directive anwyay, so we have to
resort to __always_inline when we disagree.

I queued this as a fix against
userns-allow-ptrace-from-non-init-user-namespaces.patch, but I get the
feeling that it would be better to just drop everything and start
again?

Sure, I'll rebase and resend. I wonder if I should trim the Cc list
for the next round.

thanks,
-serge

I suppose so. We've totally screwed that pooch in the VFS (grep EXPORT fs/inode.c). But it's never to late to start.
