The "check both memcg&global dirty limit" looks much more sane than the V3 implementation. Although it still has misbehaviors in some cases, it's generally a good new feature to have.

Acked-by: Wu Fengguang <fengguang.wu@intel.com>

~~~~~

To be exact, it tries to throttle the dirty speed so that vm\_dirty\_ratio is not exceeded. In fact balance\_dirty\_pages() starts throttling the dirtier slightly below vm\_dirty\_ratio.
